Emotion is a Pain in the Anterior Cingulate.

By Max Sutherland

An area of the brain that is activated by both pain and hurt feelings points a new direction for understanding links between emotion and pain. Emotional hurt may be a form of ‘pain’ signal from the anterior cingulate cortex.

If your feelings are hurt, would it help to take Tylenol?

Strange as it may seem, physical injuries and hurt feelings activate the same regions of the brain. The pain from injuries and the pain from hurt feelings are highly related and analgesics (pain relievers like Tylenol) seem to give a temporary reduction in sensitivity to that pain.

Let me quickly warn that indiscriminate use of analgesics has negative side effects and it is far too early to be conclusive about this so, the first message is...do not try this at home.

However, a paper published recently in Psychological Inquiry got my attention. It reports path-breaking research that could influence the consumption and role of pain relievers. That, in itself raises huge issues but the research also helps us, indirectly, to understand more about emotions and their evolutionary origin.

The Research
DeWall et al. (2008a) randomly assigned participants to take either a placebo or Tylenol twice daily for 21 days and report each day on the extent to which they experienced hurt feelings. Participants who were taking Tylenol gradually reported less intense hurt feelings. By the 15th day in the study, those taking Tylenol reported significantly less hurt feelings than those taking placebo, an effect that grew stronger each day to the end of the study. Just as Tylenol dampens sensitivity to pain, it seems to raise the ‘pain’ threshold for hurt feelings.

This finding was extended by another, separate study. When chronically anxious people took Tylenol, amazingly it began to lift their feelings of social self-esteem. One can only speculate that it reduced their sensitivity to the cuts inflicted by social pain, making them feel better about themselves. If these studies can be independently replicated, the implications are far reaching.

Understanding Evolutionary Alert Signals
Pain is a biological, alert signal essential for the survival of the species. While a few humans (through injury or congenital abnormality) never experience pain, they only survive in a perpetual state of mortal danger. Imagine resting your hand on something dangerously hot with no signal to tell you that your flesh is disintegrating. Pain alerts us when something physical is not right.

Pain and Emotion
A number of emotions also, alert us when something mentally is not right. When relationships or interactions fail to go as we want, we feel irritation, frustration, disappointment, sadness and hurt. But aren’t they all just emotions? What’s the connection with pain?
By alerting the mind when something physical is not right, pain stimulates the necessary attention. Many emotions (like frustration, irritation, disappointment, etc) are likewise reactions to mental things not going right. They also serve to focus attention on the source.

It seems a radical idea that the signal from mental things ‘going wrong’ is related to the signal for physical things going wrong. But the idea is not new. Gray (1987) was the first to argue for a kind of neurological overlap.\(^5\) He suggested that the unexpected loss of, or failure to obtain a desired reward promotes similar emotional experience as the presence of a threatening stimulus, including pain.

It is well known that threats trigger the amygdala but more recently brain scan evidence has revealed that pain itself is associated with activity in an area called the anterior cingulate cortex (ACC). Revealingly, even when we experience the sudden loss of an expected reward our brains react by activating this same pain region.\(^6\)

According to Eisenberger and Lieberman (2004) the function of this brain region is to detect discrepancies, such as those between desired and actual conditions. It triggers an alarm or warning signal that disrupts attention to refocus us on the source of the threat.\(^7\) However, this same brain area (ACC) is also activated when we experience these other emotions that are prompted by things that are unexpected. Even surprise activates it. Surprise is yet another response to discrepancy or mismatch and indeed, in some circles it is regarded as an emotion (albeit a more affectively neutral one).

What emerges is a view of the ACC as the centre of a common, neural alarm system - not just for pain but also for discrepancy, inconsistency and uncertainty. There is accumulating evidence that evolution may have adapted this discrepancy-sensing mechanism from simply triggering pain to also serving these emotional alert signals like surprise, irritation, frustration etc. In other words, these seem to be built on top of, or evolved from the same mechanism.

**Conclusion**

It may help to think about this as a signal-spectrum that ranges from feeling pain at one end to something affectively neutral at the other, like feeling ‘uncertainty or surprise’ (or even cognitive dissonance). In between are a number of emotions of varying intensity. When this signal indicates that all is not well physically, it is experienced as pain whereas at the other end, it is felt as cognitive discrepancy i.e. uncertainty, surprise or cognitive dissonance. Especially with interpersonal interactions, the signal is likely to be felt somewhere in the middle as emotional hurt.

In other words, think of this as a dimension of different forms of ‘pain’ emanating from a common ‘alarm’ center, located in the anterior cingulate cortex.\(^8\)

Notes:

8 Even humor is one of those emotions that is related. I pointed out in *False Alarm Theory - How Humorous Ads Work* that when humor triggers attention, it does so via this same mechanism as threatening stimuli. But instead of the signal prompting 'flight or fright', its *cancellation* triggers another signal, laughter (a primitive false-alarm signal) and the relief (like scratching an itch) can be enjoyable."
